## IN THE UNITED STATES PATENT AND TRADEMARK OFFICE

1	ABSTRACT
2	A lock for earthquakes that securely holds a door closed when an earthquake
3	strikes, but it otherwise out of the way during normal use. It consists of a steel ball that
4	is positioned at the top of an angled ramp. A magnet is embedded on the inside surface
5	of the door, where it is invisible under normal use. When an earthquake strikes, the
6	steel ball drops and contacts the magnet. At this point, the door is effectively locked.
7	The system is designed so that the magnet is strong enough to securely hold the door
8	closed, but can be easily overcome to open the door after the event is over. Once the
9	event is over, the system can be rest by pulling the door open with enough force to

overcome the magnet and placing the ball back up into its ready position. When closed,

the cabinets appear to be perfectly normal.
